Abstract. *Electric-vehicle (EV) charging networks rely on protocols like ISO 15118 and OCPP, which introduces security risks if traffic is not monitored continuously. We build a real-time intrusion detection system tailored to EV charging that uses online Adaptive Random Forest plus ADWIN to track concept drift. The system operates on streaming network traffic and updates itself on the fly, avoiding expensive retraining. Evaluated on CICEVSE2024, it achieves ~99.1% accuracy (binary) and ~98.4% (multiclass), maintains high precision/recall during drift, and processes events in ~0.0037 s each – suitable for deployment at or near charge points. We outline a clean architecture and discuss how protocol context helps flag abnormal behavior.*

Keywords: *Electric Vehicle Charging Systems, Intrusion Detection, Online Learning, Network Security, Smart Grid.*

Introduction

The global adoption of electric vehicles (EVs) is accelerating rapidly, driven by advances in battery technology, environmental goals, and government incentives. This growth has led to a corresponding expansion of Electric Vehicle Charging Systems (EVCS), which form a critical component of the emerging smart grid ecosystem. EV charging infrastructures rely on intelligent communication among vehicles, charging stations, and cloud-based management systems to ensure efficient energy distribution and billing. Protocols such as the Open Charge Point Protocol (OCPP), Open Charge Point Interface (OCPI), and ISO 15118 facilitate interoperability across manufacturers and service providers. However, these protocols also introduce significant cybersecurity vulnerabilities, as malicious actors may exploit communication channels to disrupt service, manipulate billing data, or gain unauthorized access to user and network resources [1].

Traditional Intrusion Detection Systems (IDSs) are generally trained on static datasets and are therefore unable to adapt to the evolving characteristics of cyberattacks and network behaviors. In the context of EVCS, where data streams are continuous and non-stationary, this limitation becomes critical. Attack patterns can change due to firmware updates, new communication standards, or shifts in user behavior, leading to a phenomenon known as concept drift—where the statistical distribution of data changes over time. Static IDS models degrade quickly under these conditions, resulting in reduced detection accuracy and delayed threat response [2].

To address these challenges, online machine learning techniques have gained attention for their ability to learn incrementally from streaming data without full retraining. Among these, the Adaptive Random Forest (ARF) algorithm, combined with Adaptive Windowing (ADWIN) drift detection, has demonstrated strong potential for real-time adaptation. ARF maintains an ensemble of decision trees that dynamically evolve as new data arrive, while ADWIN monitors performance metrics to identify and react to drift events automatically. This combination provides a robust mechanism to detect emerging threats in near real-time with minimal computational overhead.

Methods

The proposed intrusion detection framework is designed to identify cyberattacks in Electric Vehicle Charging Systems (EVCS) using real-time, adaptive learning. It operates as a continuous processing pipeline that collects network traffic, prepares it for analysis, and updates its model incrementally to detect both known and emerging threats. The system focuses on communications

based on ISO 15118 and OCPP protocols, where dynamic message exchanges between vehicles, chargers, and backend servers are common.

The framework was developed and evaluated using the CICEVSE2024 dataset, which contains labeled network traffic from real EV charging sessions, including both benign and multiple attack types. The data were cleaned to remove redundant and incomplete entries, normalized to ensure consistent scaling across features, and encoded into a numerical format suitable for machine learning. This preprocessing ensured that the model could operate efficiently in a streaming environment without retraining from scratch [3].

At the core of the framework lies the Adaptive Random Forest (ARF) algorithm, an ensemble of incremental decision trees capable of updating in real time as new data arrive. Each tree contributes a partial decision, allowing the ensemble to maintain high predictive accuracy while adapting to evolving data distributions. To handle changing attack patterns, the model integrates ADWIN (ADaptive WINdowing), a drift detection method that monitors performance and automatically triggers model updates when significant shifts in data are detected. This mechanism enables the IDS to remain accurate under non-stationary network conditions.

The framework’s performance was evaluated through binary (attack vs. normal) and multiclass (specific attack type) classifications. Key metrics included accuracy, precision, recall, and F1-score, along with processing latency per data instance. The system achieved an average accuracy of 99.1% for binary and 98.4% for multiclass detection, while maintaining an inference time of about 0.0037 seconds per instance, confirming its capability for real-time operation. The proposed approach thus provides a practical and scalable solution for safeguarding EV charging infrastructures against evolving cyber threats.

Experimental Results

The proposed real-time intrusion detection framework was evaluated using the CICEVSE2024 dataset, which represents realistic communication traffic in electric vehicle charging systems. The experiments were designed to test the model’s detection accuracy, adaptability to changing data patterns, and computational efficiency under streaming conditions. All experiments were conducted using Python-based implementations of the Adaptive Random Forest (ARF) and ADWIN algorithms on a standard workstation with an Intel i7 processor and 16 GB of RAM.

Table 1: Performance Comparison of Models

The dataset was streamed sequentially to the model to simulate real-time network traffic. The data included both normal operational messages and multiple categories of malicious traffic such as denial-of-service, false data injection, and replay attacks. The model was trained incrementally, updating its internal trees as new instances arrived. This approach allowed the system to adapt dynamically without retraining from scratch, maintaining consistent performance even as the underlying data distribution changed [4].

The results show that the proposed method achieves high accuracy and robustness across both binary and multiclass detection tasks. For binary classification, distinguishing between benign and malicious events, the model reached an average accuracy of 99.1%, with a precision of 99.9%, recall of 99.1%, and an F1-score of 99.6%. For multiclass classification, which identifies specific attack types, the system achieved an overall accuracy of 98.4% and an average F1-score of 98.3%. These outcomes confirm that the model can correctly identify a wide range of attacks with minimal false positives or missed detections (Table 1).

In addition to accuracy, computational performance was evaluated to ensure the framework's suitability for real-time deployment. The average processing time per instance was approximately 0.0037 seconds, demonstrating that the model can handle continuous, high-volume data streams without introducing significant latency. The integration of ADWIN further improved adaptability, allowing the system to recover rapidly from concept drift events while sustaining accuracy levels above 98% throughout all drift scenarios [1].

Conclusions

This study presented a real-time intrusion detection framework designed to enhance the cybersecurity of Electric Vehicle Charging Systems (EVCS) using online adaptive machine learning. The proposed approach combines the Adaptive Random Forest (ARF) algorithm with the ADWIN drift detection method to enable continuous learning and automatic adaptation to evolving attack patterns. By processing network traffic in a streaming fashion, the framework eliminates the need for complete retraining, reducing computational overhead and improving responsiveness to concept drift in dynamic charging environments.
